This is particularly significant for studying macromolecular complexes and cellular structures, revealing details of protein function and assembly that are impossible to obtain with traditional electron microscopy methods. Cryo-EM has revolutionized structural biology, playing a crucial role in determining the structures of numerous proteins and viruses.
- **Scanning Transmission Electron Microscopy (STEM):** STEM uses a finely focused electron beam to scan across a sample, collecting scattered electrons to form an image. This technique allows for high-resolution imaging of both the surface and interior of a sample, offering complementary information to TEM. STEM-based techniques like **electron energy loss spectroscopy (EELS)** and **energy-dispersive X-ray spectroscopy (EDS)** provide chemical information about the sample at the nanoscale.

Frequently Asked Questions (FAQs)

Q1: What is the difference between TEM and SEM?

A1: Transmission electron microscopy (TEM) transmits electrons through a thin sample to form an image, revealing internal structures. Scanning electron microscopy (SEM) scans the surface of a sample with a focused electron beam, generating images based on the emitted electrons, providing high-resolution surface details.

Q2: How does cryo-EM work?

A2: Cryo-EM rapidly freezes a biological sample in a thin layer of vitreous ice, preserving its native structure. The frozen sample is then imaged using an electron microscope, and numerous images are computationally combined to reconstruct a 3D model of the sample.
